

Yale

Reminders

- Final exam: Saturday May 7 at 2pm in SPL 59
- Assignment 3 due tonight
- Assignment 4 (last!) out today
- Quiz 4 (last!) next Wednesday

Reminders

- Final exam: Saturday May 7 at 2pm in SPL 59
- Assignment 3 due tonight
- Assignment 4 (last!) out today
 - Graph neural nets
 - Policy gradient
 - Deep Q-Learning
 - Recurrent neural networks
- Quiz 4 (last!) next Wednesday

Reminders

- Final exam: Saturday May 7 at 2pm in SPL 59
- Assignment 3 due tonight
- Assignment 4 (last!) out today
 - Graph neural nets
 - Policy gradient
 - Deep Q-Learning
 - Recurrent neural networks
- Quiz 4 (last!) next Wednesday
 - RL concepts

Outline

- Policy iteration and gradients (recap)
- Combining policy and value estimation
- Actor-critic methods
- Neuroscience connection
- Demo: Cartpole

Main reference: "Reinforcement Learning: An Introduction" (Second Edition), Richard S. Sutton and Andrew G. Barto

Recall: Autograd

- For supervised problems, loss function is $F(\widehat{Y}, Y)$
- Can program this directly
- Often RL loss functions are built up dynamically
- Automatic differentiation allows us to handle this

https://www.tensorflow.org/guide/autodiff

4

Automatic differentiation: Hello world!

```
In [1]: import numpy as np
import tensorflow as tf

In [2]: x = tf.Variable(3.0)
    with tf.GradientTape() as tape:
        y = x**2
    dy_dx = tape.gradient(y, x)
    print(dy_dx.numpy())

6.0
```

Automatic differentiation: Hello world!

```
In [3]: w = tf.Variable(tf.random.normal((3, 2)), name='w')
        b = tf.Variable(tf.zeros(2, dtype=tf.float32), name='b')
        x = [[1., 2., 3.]]
        with tf.GradientTape() as tape:
            v = x @ w + b
            loss = tf.reduce mean(y**2)
        [dloss dw, dloss db] = tape.gradient(loss, [w, b])
        print(dloss dw.numpy(), "\n\n", dloss db.numpy())
        [[2.3997068 0.70033383]
         [4.7994137 1.4006677 ]
         [7.1991205 2.1010015 ]]
         [2.3997068 0.70033383]
```

Automatic differentiation: Gradient updates

Parameters are then updated as shown here:

```
In [4]: opt = keras.optimizers.Adam(learning_rate=0.001)
    _ = opt.apply_gradients(zip([dloss_dw, dloss_db], [w, b]))
```

We encourage you to experiment with this.

7

- The rewards are independent and noisy
- Arm k has expected payoff μ_k with variance σ_k^2 on each pull
- Each time step, pull an arm and observe the resulting reward
- Played often enough, can estimate mean reward of each arm
- What is the best policy?
- Exploration-exploitation tradeoff

We'll treat this as an RL problem and hit it with a big hammer: Deep Q-learning

Note: Contextual bandits is a framework very similar to RL

7

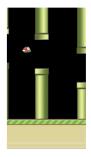

```
====episode 10000 =====

```

Please review the notebook from last class

Assn 4: Flappy Bird

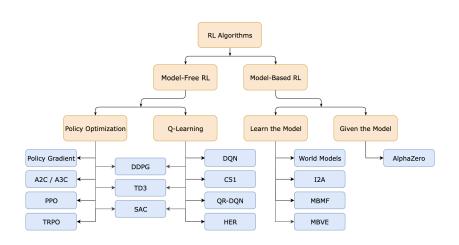

Problem 3: Deep Q-Learning for Flappy Bird (25 points)

In this problem, we will walk you through the implementation of deep Q learning to learn to play the Flappy Bird game.

Assignment 3 will feature a more involved example

Landscape of RL algorithms

Policy iteration: Idea

- 0. Initialize policy arbitrarily
- 1. Compute values for current policy (policy evaluation)
- 2. Update policy to match values (policy improvement)
- 3. Go to 1.

This will compute an optimal policy—it will satisfy Bellman's equations. Step 2. can only increase the value of the policy.

Policy iteration: Algorithm

Policy Iteration (using iterative policy evaluation) for estimating $\pi \approx \pi_*$

1. Initialization

$$V(s) \in \mathbb{R}$$
 and $\pi(s) \in \mathcal{A}(s)$ arbitrarily for all $s \in \mathcal{S}$

2. Policy Evaluation

$$\begin{aligned} & \text{Loop:} \\ & \Delta \leftarrow 0 \\ & \text{Loop for each } s \in \mathbb{S}: \\ & v \leftarrow V(s) \\ & V(s) \leftarrow \sum_{s',r} p(s',r \mid s,\pi(s)) \big[r + \gamma V(s') \big] \\ & \Delta \leftarrow \max(\Delta, |v - V(s)|) \end{aligned}$$

until $\Delta < \theta$ (a small positive number determining the accuracy of estimation)

3. Policy Improvement

$$policy\text{-}stable \leftarrow true$$

For each
$$s \in S$$
:

$$old\text{-}action \leftarrow \pi(s)$$

$$\pi(s) \leftarrow \operatorname{arg\,max}_a \sum_{s',r} p(s',r|s,a) [r + \gamma V(s')]$$

If $old\text{-}action \neq \pi(s)$, then $policy\text{-}stable \leftarrow false$

If policy-stable, then stop and return $V \approx v_*$ and $\pi \approx \pi_*$; else go to 2

Policy iteration

- As for vanilla Q-learning, this only works for small state spaces
- A "tabular" method, computes all values V(s) and actions $\pi(s)$

Policy gradient methods: Loss function

We start with the loss function: Expected reward $\mathcal{J}(\theta) = \mathbb{E}(R)$

- Parameterize the policy— $\pi(s; \theta)$ —and use features of states
- Perform gradient ascent of $\mathcal{J}(\theta)$
- Well-suited to deep learning approaches

Policy gradient methods: Loss function

Policy is probability distribution $\pi_{\theta}(a \mid s)$ over actions given state s.

The episode unfolds as a random sequence

$$\tau: (s_0,a_0) \rightarrow (s_1,r_1,a_1) \rightarrow (s_2,r_2,a_2) \rightarrow \cdots \rightarrow (s_T,r_T,a_T) \rightarrow s_{T+1}$$

where s_{T+1} is a terminal state; reward $R(\tau)$, for example

$$R(\tau) = \sum_{t=1}^{T} r_t$$

Expected reward

$$\mathcal{J}(\theta) = \mathbb{E}_{\theta}(R(\tau))$$

Calculating the gradient

Using Markov property, calculate $\mathbb{E}_{\theta}(R(\tau))$ as

$$\mathbb{E}_{\theta}(R(\tau)) = \int p(\tau \mid \theta) R(\tau) d\tau$$

$$p(\tau \mid \theta) = \prod_{t=0}^{T} \pi_{\theta}(a_t \mid s_t) p(s_{t+1}, r_{t+1} \mid s_t, a_t)$$

If states or rewards are finite the integral becomes a sum, or a mix of sums and integrals.

Calculating the gradient

Using Markov property, calculate $\mathbb{E}_{\theta}(R(\tau))$ as

$$\mathbb{E}_{\theta}(R(\tau)) = \int p(\tau \mid \theta) R(\tau) d\tau$$

$$p(\tau \mid \theta) = \prod_{t=0}^{T} \pi_{\theta}(a_t \mid s_t) p(s_{t+1}, r_{t+1} \mid s_t, a_t)$$

If states or rewards are finite the integral becomes a sum, or a mix of sums and integrals. It follows that

$$abla_{ heta} \log p(au \,|\, heta) = \sum_{t=0}^{T}
abla_{ heta} \log \pi_{ heta}(a_t \,|\, s_t) = \sum_{t=0}^{T} rac{
abla_{ heta} \pi_{ heta}(a_t \,|\, s_t)}{\pi_{ heta}(a_t \,|\, s_t)}$$

Calculating the gradient

Now we use

$$egin{aligned}
abla_{ heta} \mathcal{J}(heta) &=
abla_{ heta} \mathbb{E}_{ heta} R(au) \\ &=
abla_{ heta} \int R(au) \, p(au \, | \, heta) \, d au \\ &= \int R(au) \,
abla_{ heta} p(au \, | \, heta) \, d au \\ &= \int R(au) \, rac{
abla_{ heta} p(au \, | \, heta)}{p(au \, | \, heta)} \, p(au \, | \, heta) \, d au \\ &= \mathbb{E}_{ heta} \Big(R(au)
abla_{ heta} \log p(au \, | \, heta) \Big) \end{aligned}$$

16

Why is this important?

- This manipulation is important because it gets the policy explicity into the objective function
- Similar to the "reparameterization trick" for VAEs

Approximating the gradient

We can approximate this by sampling:

$$egin{aligned}
abla_{ heta} \mathcal{J}(heta) &pprox rac{1}{N} \sum_{i=1}^{N} R(au^{(i)})
abla_{ heta} \log p(au^{(i)} \mid heta) \ &= rac{1}{N} \sum_{i=1}^{N} R(au^{(i)}) \sum_{t=0}^{T}
abla_{ heta} \log \pi_{ heta}(a_{t}^{(i)} \mid s_{t}^{(i)}) \ &\equiv \widehat{
abla_{ heta} \mathcal{J}(heta)} \end{aligned}$$

Approximating the gradient

We can approximate this by sampling:

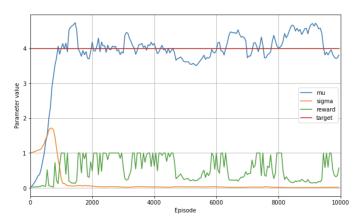

$$egin{aligned}
abla_{ heta} \mathcal{J}(heta) &pprox rac{1}{N} \sum_{i=1}^{N} R(au^{(i)})
abla_{ heta} \log p(au^{(i)} \,|\, heta) \ &= rac{1}{N} \sum_{i=1}^{N} R(au^{(i)}) \sum_{t=0}^{T}
abla_{ heta} \log \pi_{ heta}(a_{t}^{(i)} \,|\, s_{t}^{(i)}) \ &\equiv \widehat{
abla_{ heta} \mathcal{J}(heta)} \end{aligned}$$

The policy gradient algorithm is then

$$\theta \longleftarrow \theta + \alpha \widehat{\nabla_{\theta} \mathcal{J}(\theta)}$$

18

Demo

Let's go to the notebook

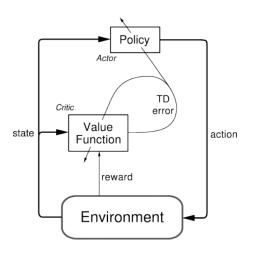

Actor-critic approaches: Idea

- Estimate policy and value function together
- Actor: policy used to select actions
- Critic: value function used to criticize actor
- Error signal from the critic drives all learning
- An on-policy approach

- After each selected action, critic evaluates new state
- Have things gone better or worse than expected?
- The error signal is used to update actor and value function

Sutton

Error signal is

$$\delta_t = r_{t+1} + \gamma V(s_{t+1}) - V(s_t)$$

 $\delta_t > 0$: action was better than expected

 δ_t < 0: action was worse than expected

Error signal is

$$\delta_t = r_{t+1} + \gamma V(s_{t+1}) - V(s_t)$$

Value function is updated as

$$V(s_t) \leftarrow V(s_t) + \alpha \delta_t$$

Error signal is

$$\delta_t = r_{t+1} + \gamma V(s_{t+1}) - V(s_t)$$

Used to update parameters of policy.

If δ_t is positive (negative), action a_t should become more (less) probable in state s_t

For example, with

$$\pi_{\theta}(a \mid s) = \operatorname{Softmax} \Big\{ f_{\theta}(s, a_1), \dots, f_{\theta}(s, a_D) \Big\}$$

parameters θ adjusted so $f_{\theta}(s_t, a_t)$ increases (decreases)

Error signal is

$$\delta_t = r_{t+1} + \gamma V(s_{t+1}) - V(s_t)$$

Used to update parameters of policy.

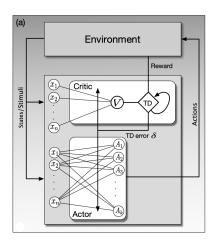

For example, with

$$\pi_{\theta}(a \mid s) = \text{Softmax}\Big\{f_{\theta}(s, a_1), \dots, f_{\theta}(s, a_D)\Big\}$$

parameters θ adjusted so $f_{\theta}(s_t, a_t)$ increases (decreases)

$$f_{\theta}(s_t, a_t) \leftarrow f_{\theta}(s_t, a_t) + \beta \delta_t$$

CartPole-v0

A pole is attached by an un-actuated joint to a cart, which moves along a frictionless track. The system is controlled by applying a force of +1 or -1 to the cart. The pendulum starts upright, and the goal is to prevent it from falling over. A reward of +1 is provided for every timestep that the pole remains upright. The episode ends when the pole is more than 15 degrees from vertical, or the cart moves more than 2.4 units from the center.

Summary: Actor-critic RL

- Estimate policy and value function together
- Actor: policy used to select actions
- Critic: value function used to criticize actor
- Error signal from the critic drives all learning
- Connections to neuroscience of behavior and reward
